The attached tables present HRG's outcome data for the year 2008.

Patient Satisfaction

HRC measures client satisfaction using the CSQ-81. The CSQ-8 consists of eight questions measuring the client's overall level of satisfaction with the services and treatment they received while in program.

Pain Level

Pain level is determined on both intake and discharge, using a "0 – 10" numeric pain rating scale where "0" is "no pain" and "10" is "worst pain ever experienced".

Pain Medication

If patients are interested in reducing or eliminating pain medication due to side effects, we will assist them in this endeavour. At the end of treatment, 82.5% were able to either reduce or eliminate their pain medication. We increased pain medication for a small number (1%).

Depression / Anxiety

Depression and anxiety are measured both at intake and discharge using the Hospital Anxiety and Depression Scale (HADS). This is a self-rating scale, free from the usual somatic indices of depression and anxiety and was normed on a hospital population, so it is a more relevant measure of emotional state in the chronic pain population than other measures.

Functional Status

Our program has a strong return to work focus and most patients who come to the program feel that they would like to rejoin the workforce if work were available and they were able to do it. Unfortunately, more than two years after the onset of their disability, most of our patients are not job attached and, therefore, the majority are discharged back to retraining. In total, 72% were able to pursue their vocational goals, which is a high rate of success for this population.
